

Operators in C

An operator is a symbol that tells the compiler to perform specific mathematical or logical manipulations. C language is rich in built-in operators and provides the following types of operators:

1. Arithmetic Operators
2. Relational Operators
3. Logical Operators
4. Assignment Operators
5. Increment and decrement operators
6. Conditional operators
7. Misc Operators

1. **Arithmetic operator:** These are used to perform mathematical calculations like addition, subtraction, multiplication, division and modulus.

Operator	Description	Example	Result
`+`	Adds two operands	`a + b`	Sum of `a` and `b`
`-`	Subtracts the second operand from the first	`a - b`	Difference of `a` and `b`
`*`	Multiplies two operands	`a * b`	Product of `a` and `b`
`/`	Divides the first operand by the second	`a / b`	Quotient of `a` and `b`
`%`	Returns the remainder of the division of two operands	`a % b`	Remainder of `a` divided by `b`

```
c Copy code
#include <stdio.h>

int main() {
    int a = 10;
    int b = 3;
    int sum, difference, product, quotient, remainder;

    sum = a + b;
    difference = a - b;
    product = a * b;
    quotient = a / b;
    remainder = a % b;

    printf("a = %d, b = %d\n", a, b);
    printf("Sum: %d + %d = %d\n", a, b, sum);
    printf("Difference: %d - %d = %d\n", a, b, difference);
    printf("Product: %d * %d = %d\n", a, b, product);
    printf("Quotient: %d / %d = %d\n", a, b, quotient);
    printf("Remainder: %d %% %d = %d\n", a, b, remainder);

    return 0;
}
```

Output:

```
makefile Copy code
a = 10, b = 3
Sum: 10 + 3 = 13
Difference: 10 - 3 = 7
Product: 10 * 3 = 30
Quotient: 10 / 3 = 3
Remainder: 10 % 3 = 1
```

&  
Test Series**

**Introduction to 'C' Language - Module 2**

2. **Relational Operators:** These operators are used to compare the value of two variables.

**Relational Operators**

Operator	Description	Example	Result
`==`	Checks if two operands are equal	`a == b`	True if `a` is equal to `b`, else false
`!=`	Checks if two operands are not equal	`a != b`	True if `a` is not equal to `b`, else false
`>`	Checks if the first operand is greater than the second	`a > b`	True if `a` is greater than `b`, else false
`<`	Checks if the first operand is less than the second	`a < b`	True if `a` is less than `b`, else false
`>=`	Checks if the first operand is greater than or equal to the second	`a >= b`	True if `a` is greater than or equal to `b`, else false
`<=`	Checks if the first operand is less than or equal to the second	`a <= b`	True if `a` is less than or equal to `b`, else false

### Program in C for Relational Operators

```
#include <stdio.h>

int main() {
    int a, b;

    // Reading two integers from the user
    printf("Enter the first integer: ");
    scanf("%d", &a);
    printf("Enter the second integer: ");
    scanf("%d", &b);

    // Checking if the two operands are equal using ==
    if (a == b) {
        printf("%d is equal to %d\n", a, b);
    } else {
        printf("%d is not equal to %d\n", a, b);
    }

    // Checking if the two operands are not equal using !=
    if (a != b) {
        printf("%d is not equal to %d\n", a, b);
    } else {
        printf("%d is equal to %d\n", a, b);
    }

    // Checking if the first operand is greater than the second using >
    if (a > b) {
        printf("%d is greater than %d\n", a, b);
    } else {
        printf("%d is not greater than %d\n", a, b);
    }

    return 0;
}
```

Output:

```
vbnet Copy code
Enter the first integer: 10
Enter the second integer: 20
10 is not equal to 20
10 is not equal to 20
10 is not greater than 20
```

**3. Logical Operators:** These operators are used to perform logical operations on the given two variables.

**Logical AND (&&):**

- Usage: a && b
- Description: Evaluates to true if both a and b are true.
- Example: If a is true and b is true, then a && b is true. Otherwise, it is false.

**Logical OR (||):**

- Usage: a || b
- Description: Evaluates to true if at least one of a or b is true.
- Example: If a is true or b is true, then a || b is true. If both are false, then a || b is false.

**Logical NOT (!)**

- Usage: !a
- Description: Evaluates to true if a is false.
- Example: If a is false, then !a is true. If a is true, then !a is false.

## Introduction to 'C' Language - Module 2

Output:

```
sql Copy code  
  
Enter the first integer: 10  
Enter the second integer: -5  
Enter the third integer: 0  
Not all three numbers are positive.  
At least one number is positive.  
At least one number is zero.
```

### Explanation:

**Input:** The program prompts the user to enter three integers using scanf.

#### Logical AND (&&):

- The program uses the && operator to check if all three integers are positive.
- If all are positive, it prints a message stating that all three numbers are positive.
- Otherwise, it prints that not all three numbers are positive.

#### Logical OR (||):

- The program uses the || operator to check if at least one of the integers is positive.
- If at least one is positive, it prints a message stating that at least one number is positive.
- Otherwise, it prints that none of the numbers are positive.

#### Logical NOT (!):

- The program uses the ! operator to check if none of the integers are zero.
- It achieves this by using the || operator within the ! operator.
- If none of the integers are zero, it prints a message stating that none of the numbers are zero.
- Otherwise, it prints that at least one number is zero.

**4. Assignment Operators:** In C programs, values for the variables are assigned using assignment operators.

**Course  
&  
Test Series**

**Introduction to 'C' Language - Module 2**

**Assignment Operators in C**

Operator	Name	Description	Example	Equivalent to
=	Assignment	Assigns the right-hand operand to the left-hand operand	a = b	-
+=	Add and Assign	Adds the right operand to the left operand and assigns the result to the left operand	a += b	a = a + b
-=	Subtract and Assign	Subtracts the right operand from the left operand and assigns the result to the left operand	a -= b	a = a - b
*=	Multiply and Assign	Multiplies the left operand by the right operand and assigns the result to the left operand	a *= b	a = a * b
/=	Divide and Assign	Divides the left operand by the right operand and assigns the result to the left operand	a /= b	a = a / b
%=	Modulus and Assign	Takes the modulus using two operands and assigns the result to the left operand	a %= b	a = a % b

c
Copy code

#include <stdio.h>

int main() {
    int a, b;

    // Reading two integers from the user
    printf("Enter the first integer (a): ");
    scanf("%d", &a);
    printf("Enter the second integer (b): ");
    scanf("%d", &b);

    // Display initial values
    printf("Initial values: a = %d, b = %d\n", a, b);

    // Add and Assign
    a += b;
    printf("After a += b: a = %d\n", a);

    // Resetting a to initial value
    a -= b; // This is to bring a back to its original value before the next operation

    // Subtract and Assign
    a -= b;
    printf("After a -= b: a = %d\n", a);

    return 0;
}
    
```

**Explanation:**

**Reading User Input:** The program prompts the user to enter two integers a and b using scanf.

**Initial Values:** The initial values of a and b are displayed.

**Add and Assign (+=):**

- a += b: Adds b to a and assigns the result to a.
- The updated value of a is displayed.

## Introduction to 'C' Language - Module 2

Resetting a:

- a is brought back to its initial value by subtracting b from the result of a += b.
- This ensures that a is restored to its original value before the next operation.

Subtract and Assign (-=):

- a -= b: Subtracts b from a and assigns the result to a.
- The updated value of a is displayed.

Output:

```
less Copy code  
  
Enter the first integer (a): 10  
Enter the second integer (b): 5  
Initial values: a = 10, b = 5  
After a += b: a = 15  
After a -= b: a = 5
```

## Increment and Decrement Operator

In C, ++ and - are called increment and decrement operators respectively. Both of these operators are unary operators, i.e, used on single operand. ++ adds 1 to operand and - subtracts 1 to operand respectively. For example:

Let a=5 and b=10

- a++; //a becomes 6
- a--; //a becomes 5
- ++a; //a becomes 6
- --a; //a becomes 5

Course  
&  
Test Series

## Introduction to 'C' Language - Module 2

### C Program Using Increment and Decrement Operators

```
c Copy code
#include <stdio.h>

int main() {
    int a;

    // Reading an integer from the user
    printf("Enter an integer: ");
    scanf("%d", &a);

    // Initial value
    printf("Initial value of a: %d\n", a);

    // Post-increment
    printf("Value after a++ (post-increment): %d\n", a++);
    printf("Value of a after post-increment operation: %d\n", a);

    // Pre-increment
    printf("Value after ++a (pre-increment): %d\n", ++a);

    // Post-decrement
    printf("Value after a-- (post-decrement): %d\n", a--);
    printf("Value of a after post-decrement operation: %d\n", a);

    // Pre-decrement
    printf("Value after --a (pre-decrement): %d\n", --a);

    return 0;
}
```

Explanation:

**Reading User Input:** The program prompts the user to enter an integer a using scanf.

**Initial Value:** The initial value of a is displayed.

**Post-Increment (a++):**

- The value of a is displayed before it is incremented by one.

**Introduction to 'C' Language - Module 2**

- The value of a is displayed again after the post-increment operation to show the updated value.

**Pre-Increment (++a):**

- The value of a is incremented by one and then the updated value is displayed.

**Post-Decrement (a--):**

- The value of a is displayed before it is decremented by one.
- The value of a is displayed again after the post-decrement operation to show the updated value.

**Pre-Decrement (--a):**

- The value of a is decremented by one and then the updated value is displayed.

**Output:**

```

mathematica Copy code
Enter an integer: 10
Initial value of a: 10
Value after a++ (post-increment): 10
Value of a after post-increment operation: 11
Value after ++a (pre-increment): 12
Value after a-- (post-decrement): 12
Value of a after post-decrement operation: 11
Value after --a (pre-decrement): 10
    
```

**Conditional Operators (? :)**

Conditional operators are used in decision making in C programming, i.e, executes different statements according to test condition whether it is either true or false.

**Syntax of conditional operators;**

conditional\_expression?expression1:expression2

- condition: The expression that is evaluated first. If this condition is true (non-zero), expression1 is evaluated and its value is returned.
- expression1: The expression that is evaluated and returned if the condition is true.

Course  
&  
Test Series

Introduction to 'C' Language - Module 2

- expression2: The expression that is evaluated and returned if the condition is false.

Example

```
c Copy code  
  
int a = 5, b = 10;  
int max;  
  
max = (a > b) ? a : b;  
printf("The maximum value is: %d\n", max);
```

In the example above, the condition  $a > b$  is evaluated:

- If  $a > b$  is true, max is assigned the value of a.
- If  $a > b$  is false, max is assigned the value of b.

## Introduction to 'C' Language - Module 2

### Finding the Maximum Value:

- The ternary operator  $(a > b) ? a : b$  is used to determine the maximum value between  $a$  and  $b$ .
- If  $a$  is greater than  $b$ ,  $\max$  is assigned the value of  $a$ ; otherwise,  $\max$  is assigned the value of  $b$ .
- The maximum value is then printed.

### Finding the Minimum Value:

- The ternary operator  $(a < b) ? a : b$  is used to determine the minimum value between  $a$  and  $b$ .
- If  $a$  is less than  $b$ ,  $\min$  is assigned the value of  $a$ ; otherwise,  $\min$  is assigned the value of  $b$ .
- The minimum value is then printed.

### Checking Even or Odd:

- The program reads an integer num from the user.
- The ternary operator  $(\text{num} \% 2 == 0) ? \text{"even"} : \text{"odd"}$  is used to check if num is even or odd.
- If  $\text{num} \% 2 == 0$  is true, "even" is printed; otherwise, "odd" is printed.

### Output

```
vbnet Copy code
Enter the first integer (a): 10
Enter the second integer (b): 5
The maximum value is: 10
The minimum value is: 5
Enter an integer to check even or odd: 7
7 is odd

**Miscellaneous Operators in C**

C provides several operators that do not fit neatly into other categories but are still widely used. These miscellaneous operators include:

- sizeof Operator
- Comma Operator

Using `sizeof` with Data Types:

```

c
#include <stdio.h>

int main() {
    printf("Size of int: %lu bytes\n", sizeof(int));
    printf("Size of float: %lu bytes\n", sizeof(float));
    printf("Size of char: %lu bytes\n", sizeof(char));
    printf("Size of double: %lu bytes\n", sizeof(double));
    return 0;
}
    
```

Using sizeof with Data Types:

- The sizeof operator returns the size of the specified data type.
- This can be useful to determine how much memory different data types occupy.

```

plaintext
Size of int: 4 bytes
Size of float: 4 bytes
Size of char: 1 byte
Size of double: 8 bytes
    
```

**Comma Operator in C**

The comma operator in C is used to separate two or more expressions, ensuring that each of the expressions is evaluated, and the result of the last expression is returned.

It's a sequence point, which means all side effects of the previous expression are completed before the next expression is evaluated.

Course  
&  
Test Series

## Introduction to 'C' Language - Module 2

Syntax of comma operator:

expression1, expression2, expression3, ..., expression

Example of Comma Operator

```

c
Copy code

#include <stdio.h>

int main() {
    int a, b;
    a = 1, b = 2; // Using comma operator to separate expressions
    printf("a = %d, b = %d\n", a, b);

    int result = (a = 3, b = 4, a + b); // Evaluating multiple expressions
    printf("Result: %d\n", result); // Result is the value of the last expression (a + b)

    return 0;
}
    
```

Explanation

Variable Initialization and Assignment: `a = 1, b = 2;` initializes `a` to 1 and `b` to 2.

First printf Statement:

- `printf("a = %d, b = %d\n", a, b);` prints the values of `a` and `b`.
- At this point, `a` is 1 and `b` is 2.

Comma Operator and Assignment:

- `int result = (a = 3, b = 4, a + b);`
- This statement performs multiple assignments and a final addition:
- `a = 3:` Assigns 3 to `a`.
- `b = 4:` Assigns 4 to `b`.
- `a + b:` Adds `a` and `b` (`3 + 4`) and assigns the result (7) to `result`.

Second printf Statement:

- `printf("Result: %d\n", result);` prints the value of `result`.
- The value of `result` is 7.

```

plaintext
Copy code

a = 1, b = 2
Result: 7
    
```
