What is Operator Overloading?

- Python allows you to **define custom behavior** for standard operators (like +, -, *, etc.) for your own classes.
- This is called **operator overloading**.
- **Why?** So that operators can work with **user-defined objects** just like they work with built-in types.

Solved Example 1: Overloading + operator

class Point:

```
def __init__(self, x, y):
    self.x = x
    self.y = y

# Overload the + operator
def __add__(self, other):
    return Point(self.x + other.x, self.y + other.y)

def display(self):
    print(f"({self.x}, {self.y})")
```

```
p1 = Point(2, 3)
p2 = Point(4, 5)
p3 = p1 + p2 # Calls p1.__add__(p2)
p3.display()
```

Output:
(6, 8)

Explanation:

- **__add__** is a **special method** in Python to define +.
- When we do p1 + p2, Python internally calls p1.**__add__**(p2).
- Result is a new **Point object** with summed coordinates.

Other Common Operators You Can Overload

Operator	Special Method
+	__add__
-	__sub__
*	__mul__
/	__truediv__

Solved Example 2: Overloading * operator for a custom class

class Number:

```
def __init__(self, value):
    self.value = value
```

```
# Overload the * operator
def __mul__(self, other):
    return Number(self.value * other.value)
```

```
def display(self):
    print(self.value)
```

```
# Create two numbers
n1 = Number(5)
n2 = Number(10)
```

```
# Multiply using * operator
n3 = n1 * n2 # Calls n1.__mul__(n2)
n3.display()
```

Output:
50

Explanation:

- The * operator is customized to multiply the values of two Number objects.
- n1 * n2 returns a new Number object with the product.

Key Points

- Enables custom behavior for operators with objects.
- Uses special methods (also called magic methods) like __add__, __sub__, __mul__.
- Helps make user-defined objects behave like built-in types.
- Supports polymorphism in object-oriented programming.
